

Adaptive Game Model - One-Page Summary

For the Sporting Director / Head Coach

Three key findings

1. Against **Final-third attack vs compact defence**, **s_third_man_combination** adds **+0.013** expected possession value per possession (CI [+0.008, +0.019]).
2. Against **Opponent high press**, **s_third_man_combination** adds **+0.011** expected possession value per possession (CI [+0.009, +0.013]).
3. Against **Final-third attack vs compact defence**, **s_reduce_risky_central_passes** adds **+0.010** expected possession value per possession (CI [-0.002, +0.020]).

The value model beats every baseline out-of-time (RMSE 0.030 vs league-average 0.032).

The system names its tactical states in coaching language and explains its failures - it is built to be questioned, not to be followed blindly.

One action

Adopt **s_third_man_combination** when the opponent shows **Final-third attack vs compact defence** - worth ~0.8 EPV across 60 possessions, at high confidence.

One risk

Medium execution risk; combinations fail under intense pressure without strong first touches.

One uncertainty

All estimates are event-based historical expectations with explicit confidence intervals; they are not guarantees. Applicability is limited to opponents and leagues in the training set, and tracking-level effects (space, timing) are not captured.
