

Adaptive Game Model - One-Page Summary

For the Sporting Director / Head Coach

Three key findings

1. Against **Neutral build-up / rest state**, **s_mid_block_retreat** adds **+0.016** expected possession value per possession (CI [+0.014, +0.020]).
2. Against **Final-third attack vs compact defence**, **s_third_man_combination** adds **+0.012** expected possession value per possession (CI [+0.005, +0.018]).
3. Against **Wide overload**, **s_aggressive_counterpress** adds **+0.008** expected possession value per possession (CI [-0.016, +0.032]).

The value model beats every baseline out-of-time (RMSE 0.052 vs league-average 0.056).

The system names its tactical states in coaching language and explains its failures - it is built to be questioned, not to be followed blindly.

One action

Adopt **s_mid_block_retreat** when the opponent shows **Neutral build-up / rest state** - worth ~1.0 EPV across 60 possessions, at medium confidence.

One risk

Concedes territorial control and gives the opponent uncontested build-up.

One uncertainty

All estimates are event-based historical expectations with explicit confidence intervals; they are not guarantees. Applicability is limited to opponents and leagues in the training set, and tracking-level effects (space, timing) are not captured.
